1.2 Acknowledgments

I would like to thank Sean Silva, chisophugis@gmail.com, for his help, encouragement, and assistance with the Sphinx document generator. Without his help, this book would not have been finished and published online. Also thanking those corrections from readers who make the book more accurate.

1.3 Build steps

<https://github.com/Jonathan2251/lbt/blob/master/README.md>

1.4 Revision history

Version 12.0.2, Not release yet.

Version 12.0.1, Release December 11, 2021.

Add target Cpu0 to clang

Version 12.0.0, Release August 11, 2021.

Version 3.9.1, Released April 29, 2020

Enable tailcall test option in build-slinker.sh

Version 3.9.0, Released November 22, 2016

Porting to llvm 3.9.

Version 3.7.4, Released September 22, 2016

Split elf2hex-dlinker.cpp from elf2hex.cpp in exlbt/elf2hex.

Version 3.7.3, Released July 20, 2016

Refine code-block according sphinx lexers. Add search this book.

Version 3.7.2, Released June 29, 2016

Dynamic linker change display from ret \$t9 to jr \$t9. Move llvm-objdump -elf2hex to elf2hex. Upgrade sphinx to 1.4.4.

Version 3.7.1, Released November 7, 2015

Remove EM_CPU0_EL. Add IR blockaddress and indirectbr support. Add ch_9_3_detect_exception.cpp test. Change display “ret \$rx” to “jr \$rx” where \$rx is not \$lr. Add Phi node test.

Version 3.7.0, Released September 24, 2015

Porting to lld 3.7.

Version 3.6.2, Released May 4, 2015

Move some test from lbt to lbd. Remove warning in build Cpu0 code.

Version 3.6.1, Released March 22, 2015 Correct typing.

Version 3.6.0, Released March 8, 2015 Porting to lld 3.6.

1.5 Licensing

1.6 Outline of Chapters

Fig. 1.1: Code generation and execution flow

The upper half of Fig. 1.1 is the work flow and software package of a computer program be generated and executed. IR stands for Intermediate Representation. The lower half is this book's work flow and software package of the toolchain extended implementation based on llvm. Except clang, the other blocks need to be extended for a new backend development. This book implement the green boxes part. The Cpu0 llvm backend can be find on <http://jonathan2251.github.io/lbd/index.html>.

This book include:

1. The elf2hex extended from llvm-objump. Chapter 2.
2. Optimization. Chapter 3.
3. Porting C standard library from avr libc and software floating point library from LLVM compiler-rt.

With these implementation, reader can generate Cpu0 machine code through Cpu0 llvm backend compiler, linker and elf2hex, then see how it runs on your computer.

Cpu0 ELF linker:

Develop ELF linker for Cpu0 backend based on lld project.

Optimization:

Backend independent optimaization.

Library:

Software floating point library and standard C library supporting. Under working.

CPU0 ELF LINKER

- *ELF to Hex*
- *Create Cpu0 backend under LLD*
 - *LLD introduction*
 - *Static linker*
 - *Dynamic linker*
- *Summary*
 - *Create a new backend base on LLVM*
 - *Contribute back to Open Source through working and learning*

LLD changes quickly and the figures of this chapter is not up to date. Like llvm, lld linker include a couple of target in ELF format handling. The term Cpu0 backend used in this chapter can refer to the ELF format handling for Cpu0 target machine under lld, llvm compiler backend, or both. But supposing readers will easy knowing what it refer to.

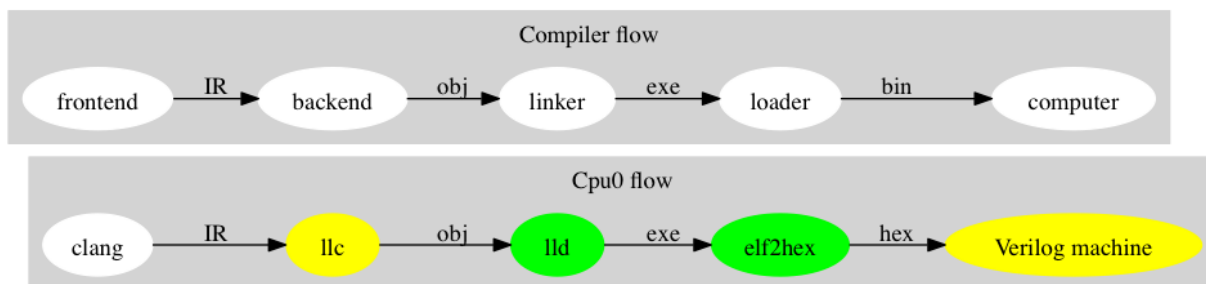

Fig. 2.1: Code generation and execution flow

As depicted in Fig. 2.1 of chapter About. Beside llvm backend, we implement ELF linker and elf2hex to run on Cpu0 verilog simulator. This chapter extends lld to support Cpu0 backend as well as elf2hex to replace Cpu0 loader. After link with lld, the program with global variables can be allocated in ELF file format layout. Meaning the relocation records of global variables is resolved. In addition, elf2hex is implemented for supporting generate Hex file from ELF. With these two tools supported, the global variables exists in section .data and .rodata can be accessed and transferred to Hex file which feeds to Verilog Cpu0 machine and run on your PC/Laptop.

As the previous chapters mentioned, Cpu0 has two relocation models for static link and dynamic link, respectively, which controlled by option `-relocation-model` in llc. This chapter supports the static link.

About lld please refer LLD web site here¹ and LLD install requirement on Linux here². Currently, lld can be built by: gcc and clang compiler on Ubuntu. On iMac, lld can be built by clang with the Xcode version as the next sub section. If you run with Virtual Machine (VM), please keep your physical memory size setting over 1GB to avoid insufficient memory link error.

2.1 ELF to Hex

As follows,

exlbt/elf2hex/CMakeLists.txt

```
# elf2hex.cpp needs backend related functions, like
# LLVMInitializeCpu0TargetInfo and LLVMInitializeCpu0Disassembler ... etc.
# Set LLVM_LINK_COMPONENTS then it can link them during the link stage.
set(LLVM_LINK_COMPONENTS
#   AllTargetsAsmPrinters
  AllTargetsDescs
  AllTargetsDisassemblers
  AllTargetsInfos
  BinaryFormat
  CodeGen
  DebugInfoDWARF
  DebugInfoPDB
  Demangle
  MC
  MCDisassembler
  Object
  Support
  Symbolize
)

add_llvm_tool(elf2hex
  elf2hex.cpp
)

if(HAVE_LIBXAR)
  target_link_libraries(elf2hex PRIVATE ${XAR_LIB})
endif()

if(LLVM_INSTALL_BINUTILS_SYMLINKS)
  add_llvm_tool_symlink(elf2hex elf2hex)
endif()

```

In order to support command, **llvm-objdump -d** and **llvm-objdump -t**, for Cpu0, the code add to **llvm-objdump.cpp** as follows,

exlbt/llvm-objdump/llvm-objdump.cpp

```
case ELF::EM_CPU0: //Cpu0
```

2.2 Create Cpu0 backend under LLD

2.2.1 LLD introduction

In general, linker do the Relocation Records Resolve as Chapter ELF support depicted, and optimization for those cannot finish in compiler stage. One of the optimization opportunities in linker is Dead Code Stripping which is explained as follows,

Dead code stripping - example (modified from llvm lto document web)

a.h

```

extern int foo1(void);
extern void foo2(void);
extern int foo4(void);

```

a.cpp

```
#include "a.h"

static signed int i = 0;

void foo2(void) {
    i = -1;
}

static int foo3() {
    return (10+foo4());
}

int foo1(void) {
    int data = 0;

    if (i < 0)
        data = foo3();

    data = data + 42;
    return data;
}
```

ch13_1.cpp

```
#include "a.h"

void ISR() {
    asm("ISR:");
    return;
}

int foo4(void) {
    return 5;
}

int main() {
    return foo1();
}
```

Above code can be reduced to [Fig. 2.2](#) to perform mark and swip in graph for Dead Code Stripping.

As above example, the foo2() is an isolated node without any reference. It's dead code and can be removed in linker optimization. We test this example by build-ch13_1.sh and find foo2() cannot be removed. There are two possibilities for this situation. One is we do not trigger lld dead code stripping optimization in command (the default is not do it). The other is lld hasn't implemented it yet at this point. It's reasonable since the lld is in its early stages of development. We didn't dig it more, since the Cpu0 backend tutorial just need a linker to finish Relocation Records Resolve and see how it runs on PC.

Remind, llvm-linker is the linker works on IR level linker optimization. Sometime when you got the obj file only (if

Fig. 2.2: Atom classified (from lld web)

you have a.o in this case), the native linker (such as lld) have the opportunity to do Dead Code Stripping while the IR linker hasn't.

2.2.2 Static linker

Let's run the static linker first and explain it next.

File printf-stdarg.c come from internet download which is GPL2 license. GPL2 is more restricted than LLVM license. File printf-stdarg-1.c is the file for testing the printf() function which implemented on PC OS platform. Let's run printf-stdarg-2.cpp on Cpu0 and compare it against the result of PC's printf() as below.

exlbt/input/printf-stdarg-1.c

```

3: 0003 zero padded
3: 3    left justif.
3:      3 right justif.
-3: -003 zero padded

```

Let's check the result with PC program printf-stdarg-1.c output as follows,

```

1-160-136-173:input Jonathan$ clang printf-stdarg-1.c
printf-stdarg-1.c:58:19: warning: incomplete format specifier [-Wformat]
    printf("%d %s(s)%", 0, "message");
                  ^
1 warning generated.
1-160-136-173:input Jonathan$ ./a.out
Hello world!
printf test
(null) is null pointer
5 = 5
-2147483647 = - max int
char a = 'a'
hex ff = ff
hex 00 = 00
signed -3 = unsigned 4294967293 = hex ffffffff
0 message(s)

```

(continues on next page)

(continued from previous page)

```
0 message(s) with \%
justif: "left      "
justif: "      right"
 3: 0003 zero padded
 3: 3    left justif.
 3: 3    right justif.
-3: -003 zero padded
-3: -3   left justif.
-3: -3   right justif.
```

They are same. You can verify the slt instructions is work fine too by change variable cpu from cpu032I to cpu032II as follows,

exlbt/input/build-printf-stdarg-2.sh

```
1-160-136-173:verilog Jonathan$ pwd
/Users/Jonathan/Download/lbdex/verilog
1-160-136-173:verilog Jonathan$ cd ../../exlbt/input
1-160-136-173:input Jonathan$ pwd
/Users/Jonathan/Download/exlbt/input
1-160-136-173:input Jonathan$ bash build-printf-stdarg-2.sh cpu032II be
...
1-160-136-173:input Jonathan$ cd ../lbdex/verilog/
1-160-136-173:verilog Jonathan$ ./cpu0IIs
```

The verilog machine cpu0IIs include all instructions of cpu032I and add slt, beq, ..., instructions. Run build-printf-stdarg-2.sh with cpu=cpu032II will generate slt, beq and bne instructions instead of cmp, jeq, ... instructions.

With the printf() of GPL source code, we can program more test code with it to verify the previous llvm Cpu0 backend generated program. The following code is for this purpose.

exlbt/input/debug.cpp

```
#include "debug.h"

extern "C" int printf(const char *format, ...);

// With read variable form asm, such as sw in this example, the function,
// ISR_Handler() must entry from beginning. The ISR() enter from "ISR:" will
// has incorrect value for reload instruction in offset.
// For example, the correct one is:
//  "addiu $sp, $sp, -12"
//  "mov $fp, $sp"
// ISR:
//  "ld $2, 32($fp)"
// Go to ISR directly, then the $fp is 12+ than original, then it will get
//  "ld $2, 20($fp)" actually.
void ISR_Handler() {
    SAVE_REGISTERS;
    asm("lui $7, 0xffff");
```

(continues on next page)

(continued from previous page)

```

asm("ori $7, $7, 0xfdf");

As above, by taking the open source code advantage, Cpu0 got the more stable printf() program. Once Cpu0 backend can translate the printf() function of the open source C printf() program into machine instructions, the llvm Cpu0 backend can be verified with printf(). With the quality code of open source printf() program, the Cpu0 toolchain is extended from compiler backend to C std library support. (Notice that some GPL open source code are not quality code, but some are.)

The “Overflow exception is printed twice meaning the ISR() of debug.cpp is called twice from ch4_1_2.cpp. The printed “taskInterrupt(001)” and “taskInterrupt(011)” just are trace message from cpu0.v code.

2.2.3 Dynamic linker

I remove dynamic linker demonstration from 3.9.0 because I don’t know how to do it from lld 3.9 and this demonstration add lots of code in elf2hex, verilog and lld of Cpu0 backend. However it can be run with llvm 3.7 with the following command.

```

1-160-136-173:test Jonathan$ pwd
/Users/Jonathan/test
1-160-136-173:test Jonathan$ git clone https://github.com/Jonathan2251/lbd
1-160-136-173:test Jonathan$ git clone https://github.com/Jonathan2251/lbt
1-160-136-173:test Jonathan$ cd lbd
1-160-136-173:lbd Jonathan$ pwd
/Users/Jonathan/test/lbd
1-160-136-173:lbd Jonathan$ git checkout release_374
1-160-136-173:lbd Jonathan$ cd ../lbt
1-160-136-173:test Jonathan$ git checkout release_374
1-160-136-173:lbt Jonathan$ make html

```

Then reading this section in lld.html for it.

2.3 Summary

2.3.1 Create a new backend base on LLVM

Thanks the llvm open source project. To write a linker and ELF to Hex tools for a new CPU architecture is easy and reliable. Combined with the llvm Cpu0 backend code and Verilog language code programmed in previous chapters, we design a software toolchain to compile C/C++ code, link and run it on Verilog Cpu0 simulator without any real hardware investment. If you buy the FPGA development hardware, we believe these code can run on FPGA CPU even though we didn’t do it. Extend system program toolchain to support a new CPU instruction set can be finished just like we have shown you at this point. School knowledges of system program, compiler, linker, loader, computer architecture

and CPU design has been translated into a real work and see how it is running. Now, these school books knowledge is not limited on paper. We design it, program it, and run it on real world.

The total code size of llvm Cpu0 backend compiler, Cpu0 lld linker, elf2hex and Cpu0 Verilog Language is around 10 thousands lines of source code include comments. The total code size of clang, llvm and lld has 1000 thousands lines exclude the test and documents parts. It is only 1 % of the llvm size. More over, the llvm Cpu0 backend and lld Cpu0 backend are 70% of same with llvm Mips and lld X86_64. Based on this truth, we believe llvm is a well defined structure in compiler architecture.

2.3.2 Contribute back to Open Source through working and learning

Finally, 10 thousands lines of source code in Cpu0 backend is very small in UI program. But it's quite complex in system program which based on llvm. We spent 600 pages of pdf to explain these code. Open source code give programmers best opportunity to understand the code and enhance/extend the code function. But it can be better, we believe the documentation is the next most important thing to improve the open source code development. The Open Source Organization recognized this point and set Open Source Document Project years ago⁷⁸⁹¹⁰¹¹. Open Source grows up and becomes a giant software infrastructure with the forces of company¹²¹³, school research team and countless talent engineers passion. It terminated the situation of everyone trying to re-invent wheels during 10 years ago. Extend your software from the re-usable source code is the right way. Of course you should consider an open source license if you are working with business. Actually anyone can contribute back to open source through the learning process. This book is written through the process of learning llvm backend and contribute back to llvm open source project. We think this book cannot exists in traditional paper book form since only few number of readers interested in study llvm backend even though there are many paper published books in concept of compiler. So, this book is published via electric media form and try to match the Open Document License Expection¹⁴. There are distance between the concept and the realistic program implemenation. Keep note through learning a large complicate software such as this llvm backend is not enough. We all learned the knowledge through books during school and after school. So, if you cannot find a good way to produce documents, you can consider to write documents like this book. This book document uses sphinx tool just like the llvm development team. Sphinx uses restructured text format here¹⁵¹⁶¹⁷. Appendix A of lld book tell you how to install sphinx tool. Documentation work will help yourself to re-examine your software and make your program better in structure, reliability and more important "Extend your code to somewhere you didn't expect".

OPTIMIZATION

- *LLVM IR optimization*
- *Project*
 - *LLVM-VPO*

This chapter introduce llvm optimization.

3.1 LLVM IR optimization

The llvm-link provide optimizatoin in IR level which can apply in different programs developed by more than one language. Of course, it can apply in the same language which support seperate compile.

Fig. 3.1: llvm-link flow

Clang provide optimization options to do optimation from high level language to IR. But since many languages like C/C++ support separate compilation, it meaning there is no chance to do inter-procedure optimization if the functions come from different source files. To solve this problem, llvm provide **llvm-link** to link all *.bc into a single IR file, and through **opt** to finish the inter-procedure optimization¹. Beyond the DAG local optimization mentioned in Chapter 2, there are global optimization based on inter-procedure analysis². The following steps and examples show this optimization solution in llvm.

¹ <http://www.cs.cmu.edu/afs/cs/academic/class/15745-s12/public/lectures/L3-LLVM-Part1.pdf>

² Refer chapter 9 of book Compilers: Principles, Techniques, and Tools (2nd Edition)

exlbt/input/optimizen/1.cpp

```
int callee(const int *a) {  
    return *a+1;  
}
```

exlbt/input/optimize/2.cpp

```
extern int callee(const int *X);  
  
int caller() {  
    int T;  
  
    T = 4;  
  
    return callee(&T);  
}
```

```
JonathantekiiMac:input Jonathan$ clang -O3 -target mips-unknown-linux-gnu  
-c 1.cpp -emit-llvm -o 1.bc  
JonathantekiiMac:input Jonathan$ clang -O3 -target mips-unknown-linux-gnu  
-c 2.cpp -emit-llvm -o 2.bc  
JonathantekiiMac:input Jonathan$ llvm-link -o=a.bc 1.bc 2.bc  
JonathantekiiMac:input Jonathan$ opt -O3 -o=a1.bc a.bc  
JonathantekiiMac:input Jonathan$ llvm-dis a.bc -o -  
...  
; Function Attrs: nounwind readonly  
define i32 @_Z6calleePKi(i32* nocapture readonly %a) #0 {  
    %1 = load i32* %a, align 4, !tbaa !1  
    %2 = add nsw i32 %1, 1  
    ret i32 %2  
}  
  
define i32 @_Z6callerv() #1 {  
    %T = alloca i32, align 4  
    store i32 4, i32* %T, align 4, !tbaa !1  
    %1 = call i32 @_Z6calleePKi(i32* %T)  
    ret i32 %1  
}  
...  
  
JonathantekiiMac:input Jonathan$ llvm-dis a1.bc -o -  
...  
; Function Attrs: nounwind readonly  
define i32 @_Z6calleePKi(i32* nocapture readonly %a) #0 {  
    %1 = load i32* %a, align 4, !tbaa !1  
    %2 = add nsw i32 %1, 1  
    ret i32 %2  
}
```

(continues on next page)

(continued from previous page)

```
; Function Attrs: nounwind readnone
define i32 @_Z6callerv() #1 {
    ret i32 5
}
...
```

From the result as above, the **opt** output has lesser number of IR instructions. Of course, the backend code will be more effective as follows,

```

```

Though `llvm-link` provide optimization in IR level to support separate compile, it come with the cost in compile time. As you can imagine, any one statement change will change the output IR of `llvm-link`. And the obj binary code have to re-compile. Compare to the separate compile for each *.c file, it only need to re-compile the corresponding *.o file only.

3.2 Project

3.2.1 LLVM-VPO

Friend Gang-Ryung Uh replace LLC compiler by `llvm` on Very Portable Optimizer (VPO) compiler toolchain. VPO performs optimizations on a single intermediate representation called Register Transfer Lists (RTLs). In other word, the system generate RTLs from `llvm` IR and it do further optimization on RTLs.

The LLVM-VPO is illustrated at his home page. Click “**6. LLVM-VPO Compiler Development - 2012 Google Faculty Research Award**” at this home page³ will get the information.

³ <http://cs.boisestate.edu/~uh/>

LIBRARY

- *Compiler-rt*
- *Avr libc*
- *Software Float Point Support*

Since Cpu0 has not hardware float point instructions, it needs soft float point library to finish the floating point operation. LLVM compiler-rt project include the software floating point library implementation, so we choose it as the implementation.

Since compiler-rt uses unix/linux rootfs structure, we fill the gap by porting avr libc.

Both the compiler-rt and avr libc porting is under going, it's not finished. The flow as follows,

Fig. 4.1: libc/softfloat library flow

The llvm-link which introduced at last chapter can be hired for optimization.

4.1 Compiler-rt

Directory libex/libsoftfloat/compiler-rt include the floating point library support for Cpu0 backend. The compiler-rt¹ version we use is llvm 3.5 release.

¹ <http://compiler-rt.llvm.org/>

4.2 Avr libc

Directory `libex/libc/avr-libc-1.8.1` include the libc porting.

AVR Libc is a Free Software project whose goal is to provide a high quality C library for use with GCC on Atmel AVR microcontrollers. AVR Libc is licensed under a single unified license. This so-called modified Berkeley license is intended to be compatible with most Free Software licenses like the GPL, yet impose as little restrictions for the use of the library in closed-source commercial applications as possible².

The source code can be download from here³. Document are here^{4,5}.

4.3 Software Float Point Support

`exlbt/input/ch_float_necessary.cpp`

```
//#include "debug.h"

extern "C" int printf(const char *format, ...);
extern "C" int sprintf(char *out, const char *format, ...);

template <class T>
T test_shift_left(T a, T b) {
    return (a << b);
}

template <class T>
T test_shift_right(T a, T b) {
    return (a >> b);
}

template <class T1, class T2, class T3>
T1 test_add(T2 a, T3 b) {
    T1 c = a + b;
    return c;
}

template <class T1, class T2, class T3>
T1 test_mul(T2 a, T3 b) {
    T1 c = a * b;
    return c;
}

template <class T1, class T2, class T3>
T1 test_div(T2 a, T3 b) {
    T1 c = a / b;
    return c;
}
```

    // In GCC, $1 is not widely used in generated code (it's used only in a few
    // specific situations), so there is no real need for users to add it to
    // the clobbers list if they want to use it in their inline assembly code.
    //
    // In LLVM, $1 is treated as a normal GPR and is always allocatable during
    // code generation, so using it in inline assembly without adding it to the
    // clobbers list can cause conflicts between the inline assembly code and
    // the surrounding generated code.
    //
    // Another problem is that LLVM is allowed to choose $1 for inline assembly
    // operands, which will conflict with the ".set at" assembler option (which
    // we use only for inline assembly, in order to maintain compatibility with
    // GCC) and will also conflict with the user's usage of $1.
    //
    // The easiest way to avoid these conflicts and keep $1 as an allocatable
    // register for generated code is to automatically clobber $1 for all inline
    // assembly code.
    //
    // FIXME: We should automatically clobber $1 only for inline assembly code
    // which actually uses it. This would allow LLVM to use $1 for inline
    // assembly operands if the user's assembly code doesn't use it.
